

Managerial Coordination in Decentralized Markets

Duoxi Li

Michael B. Wong*

February 2026

Abstract

This paper shows that centralized resource allocation can reduce the cost of incentivizing performance in otherwise decentralized markets. This benefit of centralization is largest when individual demands are volatile. However, it must be balanced against the incentive rents required by managers themselves. The resulting trade-off endogenously sorts market participants into either managerial coordination or decentralized exchange. We characterize the effects of managerial coordination on aggregate output, the division of labor, matching market flows, and the distribution of economic rents. Our findings offer a novel explanation for the prevalence of managerial coordination. Applications to professional services, global sourcing, and digital platforms are discussed.

Keywords: managerial coordination, relational contracts

1 Introduction

A fundamental puzzle in economic theory is the prevalence of managerial coordination. In many markets, buyers and producers could in principle transact directly with one another. Yet their exchange is frequently mediated by centralized agents who coordinate allocations, monitor performance, and enforce relational contracts (Alchian and Demsetz 1972). The theory of the firm has made considerable progress in modeling such manager-coordinators, but much of the existing work has focused on understanding individual relational contracts (e.g., Baker, Gibbons and Murphy 1994, 2002; Levin 2003; Malcomson 2013; Gil and Zanarone 2017). Recent work extends these frameworks to decentralized matching markets, illuminating how relational contracts arise when agents meet and contract freely (Board and Meyer-ter-Vehn 2015; Fahn and Murooka 2025). Despite these advances, a key gap remains. The literature lacks formal models that explain why centralized monitors add value by coordinating allocations in otherwise decentralized relational contracting markets.

This paper develops a tractable repeated-game model of managerial coordination in decentralized matching markets. The core of our analysis is a novel economic mechanism: in settings characterized by moral hazard and demand fluctuations, managers can reduce the cost of motivating performance by coordinating the assignment of buyers to producers. The model allows us to analyze the endogenous sorting of agents into managerial coordination and decentralized exchange. We characterize the equilibrium effects of managerial coordination on aggregate output, the division of labor, matching market flows, and the distribution of economic rents. We then illustrate how the framework can be used to analyze modern organizational forms. Our work extends the literature on intermediaries (e.g., Rubinstein and Wolinsky 1987; Biglaiser 1993; Spulber 1999) by showing how managerial coordination can arise even in the absence of search frictions or adverse selection.

Our framework is a variant of MacLeod and Malcomson (1989). Following previous models of environments with imperfect contractual enforcement, we assume that buyers cannot compel producers to exert effort using formal contracts, so buyers must motivate producers using future surplus in relational contracts. Buyers and producers meet and enter

contracts in frictionless matching markets without search delays or hidden payoff-relevant information, as in [Board and Meyer-ter-Vehn \(2015\)](#). Departing from prior models, we introduce a new feature—fluctuating buyer demand—to capture a realistic and relevant aspect of repeated business interactions ([Macchiavello and Morjaria 2015](#)). We also introduce managers who cannot themselves produce, but can manage—i.e., monitor and allocate—a large number of producers. In equilibrium, managers endogenously enter multiple relational contracts on both sides of the market, aggregate fluctuating demand, coordinate assignments, and keep track of producer performance.

The model reveals that managerial coordination involves a trade-off between demand smoothing and double marginalization. The benefit of managers is that they aggregate fluctuating buyer demand, coordinate assignments between buyers and producers, and thereby prevent producers from becoming idle or unmatched. Therefore, managers can promise longer and more productive relational contracts, thereby relaxing dynamic enforcement constraints and reducing the incentive rent needed to motivate producers to exert effort. However, managers must themselves be motivated by an additional incentive rent. The cost of managers is thus a form of double marginalization.

Because of this trade-off, it is found that buyers sort into managerial coordination and decentralized exchange. Their optimal choice depends on individual characteristics, such as their individual demand volatility. It also depends on market-level characteristics, such as market tightness. If the matching market is sufficiently tight, managers emerge as centralized contracting nexuses. Buyers with short-lived demand contract with managers. Buyers with long-lived demand contract directly with producers in a sea of decentralized pairings. [Figure 1](#) illustrates the relational contracting networks that endogenously emerge in the unique steady-state equilibrium of the exchange economy.

Comparative statics are derived regarding the determinants and impacts of managerial coordination. First, when compared to managed producers, directly contracted producers have higher average incentive pay, more dispersed pay, higher separation rates, and higher idleness. Second, the introduction of managers into an economy benefits buyers with

Figure 1: Endogenous relational contracting networks in steady-state equilibrium

fluctuating demand, but reduces the pay of producers initially earning pay premiums. As such, managerial coordination both increases and redistributes total surplus.

In an extension, we analyze the relationships between managerial coordination and specialization. We show that managed producers are more specialized and that managerial coordination increases producer specialization. Moreover, buyers are more likely to choose managerial coordination if there are gains from producer specialization. In another extension, we consider a version of the model where the producer population is exogenous, in contrast to our baseline model, where it is determined through the free entry of producers.

We discuss three empirical applications to showcase how the framework can be used to analyze modern organizational forms. Labor markets, for example, have been fundamentally altered by the rise of professional service firms that monitor and deploy large numbers of workers (e.g., legal, accounting, IT, and HR firms). A parallel revolution has reshaped international trade, where global sourcing firms (e.g., Li & Fung and Shein) increasingly manage vast supplier networks and coordinate significant shares of world production. More recently, consumer markets have been radically restructured by digital platforms like Uber and Airbnb, which allocate and monitor (i.e., manage) increasingly large numbers of independent contractors. Connections between our model and the empirical literature on professional service firms are discussed throughout the paper. As we shall show, the model generates

plausible predictions not only for the drivers of professional service outsourcing, but also for the effects of professional service firms on both workers and the labor market as a whole.

The rest of the paper proceeds as follows. Section 2 discusses related literature. Section 3 introduces our model and empirical applications. Section 4 characterizes and compares direct and managed contracts, taking matching market conditions as given. Section 5 derives the steady-state market equilibrium. Section 6 pursues extensions. Section 7 concludes.

2 Related Literature

Our paper is part of a growing literature on repeated-game models of relational contracts in decentralized matching markets (Shapiro and Stiglitz 1984; MacLeod and Malcomson 1989, 1998; Yang 2008; Board and Meyer-ter-Vehn 2015; Fahn 2017; Powell 2019; Li 2022; Fahn and Murooka 2025).¹ MacLeod and Malcomson (1989) lay the game-theoretic foundation for our modeling approach, and Board and Meyer-ter-Vehn (2015) provide a crisp treatment that we build upon. Relative to these canonical models, we introduce fluctuating demand and managers with neither intrinsic demand nor productive capability. These managers aggregate volatile demand and coordinate assignments, thereby alleviating a tension between incentive provision and flexible allocations and, in doing so, enabling trade and specialization.

Several papers studying multilateral relational contracts in fluctuating environments are particularly close. Board (2011) shows that the tension between incentive provision and flexible allocations can lead buyers to restrict the number of trading partners. Andrews and Barron (2016) show that it can cause dynamic allocations to depend on payoff-irrelevant past performance. Li and Powell (2020) highlight that a similar tension can lead agents to interact in multiple activities. We show that the same fundamental tension can instead induce agents to delegate allocation responsibilities to a centralized coordinator. To our knowledge, this paper is the first to show how a multilateral relational contracting problem endogenously gives rise to centralized managerial coordination, rather than decentralized matching.

¹For surveys of recent work on relational contracts in economics, see MacLeod (2007), Malcomson (2013), Gil and Zananone (2017), Macchiavello and Morjaria (2023), and Muehlheusser, Fahn and MacLeod (2023).

Our results can be viewed as providing a micro-founded answer to a variant of the question first posed by [Coase \(1937\)](#): Why do centralized resource allocators emerge in decentralized markets? In our environment, centralized allocators arise because they can better support high-powered relational incentives when demand is volatile and needs are specialized. Crucially, this mechanism operates even in the absence of search, bargaining, and contract-writing costs, as well as hidden information about agent types.

The model is closely related to informal intuitions in early contract-based theories of the firm. [Alchian and Demsetz \(1972\)](#) emphasized that the presence of a central contracting party who monitors performance and can exclude underperforming team members is the essence of the firm. [Jensen and Meckling \(1976, pp. 310–311\)](#) similarly argued that “contractual relations are the essence of the firm, not only with employees but with suppliers, customers, creditors, and so on,” and [Demsetz \(1988, p. 154\)](#) described the firm as a “nexus of contracts” whose key attributes are continuity of association, specialization, and managerial direction. Our model formalizes these intuitions in a dynamic setting with imperfect enforcement, clarifying when and why centralized contracting intermediaries arise to coordinate allocations.²

Similar ideas appear in the literatures on supply chain management and market institutions. [Belavina and Girotra \(2012\)](#) develop a model of relational intermediaries in supply chains with two buyers, two sellers, and non-transferable utilities. Our transferable-utility framework allows a fuller characterization of the determinants and welfare consequences of this form of intermediation. [Milgrom, North and Weingast \(1990\)](#) study private judges in medieval trade in a repeated Prisoner’s Dilemma, showing that such institutions can create trust with less observability than decentralized reputation systems.³ Our analysis follows a similar logic in using a repeated-game framework to study how institutions support cooperation, but our focus is neither historical nor legal. We instead argue that the need for trust remains pervasive even with modern courts and regulation, and that this need helps explain the

²[He \(2016\)](#) also formalizes aspects of [Alchian and Demsetz \(1972\)](#), but emphasizes a very different set of mechanisms.

³Related work on market institutions and enforcement includes [Greif \(1993, 2006\)](#), [Greif, Milgrom and Weingast \(1994\)](#), [Calvert \(1995\)](#), and [Fafchamps \(2004\)](#).

ubiquity of managerial coordination.

Our approach is distinct from the existing formal literature on the theory of the firm. We do not attempt to define what a firm is (cf. [Grossman and Hart 1986](#)) or to characterize systematic differences between intra-firm and inter-firm contracts (cf. [Baker, Gibbons and Murphy 2002](#)).⁴ Instead, we focus on the choice between managerial coordination and decentralized exchange in relational contracting environments. In the spirit of [Cheung \(1983\)](#), who argued that “it may be futile to press the issue of what is or is not a firm,” we treat firm-like organizations as points in a contractual network and ask when centralized coordination is chosen. Our contribution characterizes how such contractual networks form under imperfect enforcement and uses the resulting trade-offs to understand firm-like organizations, such as professional service firms.

We also contribute to general equilibrium models with managers. In [Lucas \(1978\)](#), managerial talent is scarce and complementary to production workers, generating high managerial pay. [Garicano \(2000\)](#) models knowledge hierarchies in which managers act as expert problem-solvers for less skilled workers.⁵ Like this literature, our model yields predictions about organizational structure and distributional outcomes. However, existing approaches largely abstract from the incentive problems that many scholars view as central to the managerial role. Our model of managers instead generates predictions about efficiency, inequality, and organizational form that are explicitly rooted in relational incentive constraints.

Finally, our paper is related to the broader literature on intermediaries. Much of this work studies middlemen who alleviate search frictions (e.g. [Rubinstein and Wolinsky 1987](#)) or adverse selection (e.g. [Biglaiser 1993](#)).⁶ In those frameworks, the Internet should have

⁴Beginning with [Coase \(1937\)](#) and [Williamson \(1971, 1975, 1985\)](#), many forces have been cataloged as determinants of firm boundaries. A prominent formal strand studies how the optimal allocation of asset ownership shapes firm boundaries ([Grossman and Hart 1986](#); [Baker, Gibbons and Murphy 2002](#); [Gibbons 2005](#)). Another explores differences between service and employment contracts, emphasizing bargaining and contract-writing costs ([Wernerfelt 1997, 2015, 2016](#); [Hart and Moore 2008](#); [Levin and Tadelis 2010](#); [Tadelis and Williamson 2013](#)) or differences between spot and relational contracting ([Simon 1951](#); [Bolton and Rajan 2003](#); [Raith 2022](#)).

⁵For a review of follow-on work, see [Garicano and Rossi-Hansberg \(2015\)](#).

⁶On search-based intermediation, see, for example, [Rubinstein and Wolinsky \(1987\)](#), [Gehrig \(1993\)](#), [Yavaş \(1994, 1996\)](#), [Rust and Hall \(2003\)](#), [Antras and Costinot \(2011\)](#), [Wright and Wong \(2014\)](#), [Nosal, Wong and Wright \(2015\)](#), [Nosal, Wong and Wright \(2019\)](#), and [Rhodes, Watanabe and Zhou \(2021\)](#). On adverse selection

radically disintermediated markets, yet intermediary firms have instead proliferated (Belavina and Girotra 2012; Bergeaud et al. Forthcoming). We formalize a different mechanism: intermediaries who overcome moral hazard by coordinating buyer–producer assignments in a relational contracting environment. This form of intermediation has received relatively little formal attention.

3 Model

Basics. Time is discrete and infinite, $\tau \in \{0, 1, \dots\}$. Buyers are heterogeneous, indexed by i , and have unit mass. Producers are identical and have measure n . Managers are identical and have a finite number K . All players are infinitely-lived. They have a common discount factor $\delta \in (0, 1)$. The measure of producers, n , is determined by endogenous entry subject to entry cost $C > 0$. Entry cost C represents training or opportunity cost.

Demand realization. At the start of each period, the demand of each buyer i , denoted as $d_{i,\tau} \in \{0, 1\}$, is realized and publicly observed.⁷ Each buyer’s demand $d_{i,\tau}$ is independently drawn following a Markov process. The demand-switching probabilities are determined by each buyer’s publicly known type $\alpha_i = (\alpha_{1i}, \alpha_{0i})$: with probability α_{1i} , buyer i ’s demand switches from 1 to 0; with probability α_{0i} , buyer i ’s demand switches back from 0 to 1. The buyers types have distribution F on $[0, 1] \times [0, 1]$.

Matching. After demand is realized, matched players may choose to separate. Buyers may then open vacancies for either producers or managers. Since managers cannot produce

and information provision by intermediaries, see, for example, Biglaiser (1993), Lizzeri (1999), Glode and Opp (2016), and Biglaiser and Li (2018). Recent models of relational contracting intermediaries emphasize different mechanisms: Fong and Li (2017) show that a non-strategic supervisor performing subjective performance reviews can deepen relational contracts, while Troya-Martinez and Wren-Lewis (2023) study managers who may receive kick-backs and show that such managers can nonetheless improve relational contracting when commitment is difficult.

⁷To focus on the relational incentives, we abstract from any adverse selection problem in the model. Therefore, when contracting with buyers, producers know whom they are dealing with and have the correct expectation of how the relationships will go.

by themselves, they fulfill buyer demand by matching with producers in turn.

The timing is as follows: (1) buyers open either manager vacancies or producer vacancies, (2) managers are matched with manager vacancies, (3) managers open producer vacancies, and (4) unmatched producers are matched with producer vacancies. Each buyer may open at most one vacancy, while managers may match with a continuum of buyers and producers.

Following Board and Meyer-ter-Vehn (2015), the matching of producer vacancies follows three axioms. First, matching is *frictionless*, meaning that all vacancies are filled subject to the managers' or the producers' participation constraints. Second, matching is *anonymous*, meaning that each producer's probability of becoming matched with a vacancy does not depend on their past behavior. The assumption of anonymous matching for producers is standard and simplifies analysis.⁸ Third, matching is *random*, i.e., unmatched producers have the same probability of becoming matched.⁹

The matching of manager vacancies is assumed to be frictionless, random, but *not* anonymous. In other words, if a manager violates its relational contract with a buyer and becomes unmatched, the buyer remembers the manager's violation and refuses to match with the manager forever. This assumption captures the idea that the market for managers is comparatively small.

We call a buyer-producer match a *direct match*, since it does not involve a manager. A buyer-manager-producer match is called a *managed match*.

Direct match. Let $t \in \{1, \dots\}$ denote the period in a match. If a buyer i matches with a producer, the remainder of the period proceeds as follows. First, the buyer makes a payment $w_{it} \geq 0$ to the producer. The producer then chooses an effort level, denoted by $e_{it} \in \{0, 1\}$. The cost of effort is given by $c(e_{it})$, where $c(0) = 0$ and $c(1) = c > 0$. The effort generates an output for the buyer only if demand is positive, so $y_{it} = y d_{it} e_{it}$. Effort and output are

⁸See, e.g., Shapiro and Stiglitz (1984); MacLeod and Malcomson (1998); Board and Meyer-ter-Vehn (2015).

⁹Board and Meyer-ter-Vehn (2015) analyzes relational contracts in a frictionless matching market where matched producers may receive on-the-job offers. They show that this leads to heterogeneous productivity across otherwise identical matches. We rule this possibility out for simplicity.

Figure 2: Structure of direct and managed contracts

observable by the buyer but are not verifiable by a court.

Managed match. If a buyer matches with a manager, she pays a service fee $p_{it} \geq 0$ to the manager. The manager chooses to assign one or none of its producers to the buyer. The manager pays w_{it} to the producer. The producer then exerts costly effort e_{it} and produces output y_{it} for the buyer. Effort and output are observable by both the buyer and the manager, but are not verifiable by a court.

Separation. Either party in a match may choose to separate from their match both after demand realization and after production. If separation occurs after demand realization, both parties can participate in the producer or manager market matching in the current period. However, if separation occurs after production, they need to wait till the next period to rematch.

Payoffs. In a direct match, the buyer's payoff is $y_{it} - w_{it}$ and the producer's is $w_{it} - c(e_{it})$ in each period t . In a managed match, the buyer's payoff is $y_{it} - p_{it}$, the manager's payoff is $p_{it} - w_{it}$, and the producer's payoff is $w_{it} - c(e_{it})$ in each period t .

Remark. This model has two key features that are not present in standard models of relational contracting in frictionless matching markets (e.g., [Shapiro and Stiglitz \(1984\)](#))

Figure 3: Timeline of a single period

At the start of the period, buyer demand is realized and publicly observed. Separations may then occur. Unmatched buyers can open manager vacancies and match with managers. Unmatched buyers and managers can then open producer vacancies and match with unmatched producers. In a direct match, the buyer pays the producer and the producer exerts effort. In a managed match, the buyer pays the manager, the manager assigns a producer to the buyer and pays the producer, and the producer then exerts effort. Separation may occur at the end of the period.

and [MacLeod and Malcomson \(1998\)](#)). First, we allow buyers to have fluctuating demand. Second, we introduce managers who can enter relational contracts with a multitude of players on both sides of the market. These managers do not have intrinsic demand or productive ability. What they can do, instead, is to match with a large set of buyers and producers, coordinate their matched producers, and monitor the producers' performance. As we will show in Section 4 below, when demand is volatile and the cost of idleness is high, managers can sustain cheaper relational contracts on both sides of the market by reassigning their producers across buyers. Buyers may therefore prefer managerial coordination to direct relational contracting.

3.1 Empirical Applications

Our model provides a lens to understand modern organizational forms that increasingly displace traditional decentralized exchange. The model's key friction—that effort is non-contractible and must be motivated by the future surplus of a relationship—is particularly salient in settings where quality is complex, performance is difficult to specify ex-ante, or legal enforcement is costly. The benefit of a manager is to aggregate fluctuating demand,

allowing for longer, more stable producer relationships that ease this incentive problem. This logic applies naturally to the three examples below, which span labor, product, and consumer markets.

Example 1 (Professional Service Firms). In many professional labor markets (e.g., legal, accounting, consulting), the core service—such as providing expert advice or representation—is inherently a non-contractible effort problem. A client cannot perfectly specify in advance the quality of legal strategy or the thoroughness of an audit, nor can they easily verify it in court. Instead, they rely on the service provider’s concern for future business to incentivize performance. The model applies to a client’s decision to either hire a specialized lawyer directly or engage a large law firm.

A client with a short-lived legal need faces a problem: if they employ a lawyer directly, the lawyer knows the relationship will end after the case, creating a severe end-game problem that undermines the promise of future surplus to motivate effort. The manager—here, the law firm—solves this by pooling the demand from many such transient clients. It can promise the managed lawyer a steady stream of future cases, conditional on good performance today. This longer "shadow of the future" lowers the incentive rent required to motivate high-quality work. The friction is not that legal contracts are unenforceable, but that the effort margin most critical to quality is not. The firm’s value, therefore, lies in its role as a stable, coordinating nexus that makes relational incentives sustainable for otherwise short-lived client demands.¹⁰

Example 2 (Supply Chain Intermediaries). A core friction in global sourcing is the difficulty of contracting on manufacturer effort regarding product quality, especially across jurisdictions with weak legal enforceability. A retailer could attempt to contract directly with a network of overseas factories. However, if the retailer’s product demand is volatile—a sudden spike for

¹⁰In the past half century, specialized, professional service firms have increasingly displaced traditional direct employees in providing a variety of services, including accounting, law, IT, security, logistics, and cleaning (Weil 2014). The literature on domestic outsourcing has argued that intermediary firms help clients overcome search frictions, redress adverse selection, circumvent wage-setting norms, and evade regulation (Autor 2009; Bernhardt et al. 2016). Few scholars, however, have carefully studied the possibility that intermediary firms may also strengthen performance incentives as centralized coordinators.

a new fashion item—the relationship with any one factory is intermittent. This intermittence weakens the factory’s incentive to invest in non-contractible quality or to prioritize the retailer’s urgent orders, as there is no reliable promise of future business.

A global sourcing firm (e.g., Li & Fung, Shein) acts as the manager. It aggregates orders from multiple, potentially fluctuating retailers, providing a stable and predictable workflow to its network of manufacturers. This stability allows the intermediary to build long-term relational contracts with producers, credibly threatening to withhold a significant stream of future business if quality slips. The contracting friction is thus two-fold: the difficulty of enforcing quality specifications across borders, and the demand volatility that would make direct bilateral relationships unsustainable. The intermediary’s coordination solves both, turning volatile aggregate demand into a stable stream of incentives for producers.¹¹

Example 3 (Digital Platforms). Digital platforms (e.g., Uber, Airbnb) provide a clear application of our manager as a central coordinator. Consider a rider needing a ride and a driver with a car; a direct transaction is possible. The key friction is that the driver’s effort—safe driving, politeness, clean car—is largely non-contractible. In a one-off spot transaction, the driver has no incentive to provide this effort beyond basic politeness. A platform like Uber, acting as the manager, aggregates demand from millions of riders, allowing it to offer drivers a stream of future trip requests.

The “manager” here doesn’t direct drivers in the traditional sense but coordinates allocation through an algorithm and monitors performance through ratings. A driver who provides poor service (low effort) risks deactivation, losing access to the platform’s entire stream of future riders. This is a powerful relational incentive enabled by the platform’s ability to pool demand. The model clarifies that the platform’s value does not primarily lie in reducing search frictions (though that exists), but in its role as a central nexus that

¹¹Scholars increasingly document the importance of intermediaries in trade. [Ahn, Khandelwal and Wei \(2011\)](#) estimate that intermediaries facilitated 20% of China’s exports in 2005, while [Bernard, Grazzi and Tomasi \(2015\)](#) find that over 25% of Italian exporters act as intermediaries, accounting for 10% of national exports. The importance of relational contracts in international trade is also increasingly recognized ([Macchiavello and Morjaria 2015, 2023](#); [Antràs and Chor 2022](#)). However, trade theory has largely focused on the role of intermediaries in overcoming search rather than trust frictions (e.g., [Antras and Costinot 2011](#)).

creates a sufficiently long-lived relationship with the driver to overcome the moral hazard inherent in each individual ride. The friction is most acute where the platform manages many short-term, anonymous transactions, making it the only feasible structure to enforce quality through the threat of exclusion from a future flow of work.¹²

4 Optimal Direct and Managed Relational Contracts

In this section we characterize optimal direct and managed relational contracts. We then analyze the buyer's choice between direct and managed relational contracts. This analysis explains why and when managed contracting may be preferred over direct contracting.

4.1 Direct Relational Contracts

We first focus on a single buyer who directly matches with a sequence of producers. The effect of other buyers is captured by the outside options available to the producers. We assume that the vacancies opened by other buyers are such that the pre-matching continuation value of a unmatched producer is stationary. Let $\bar{U} > 0$ denote the producer's pre-matching continuation value.

First, consider a buyer i in calendar time τ who is unmatched before producer matching. Suppose the buyer has demand and opens a vacancy with some continuation value U_i^1 . Since matching is frictionless, the vacancy is filled with certainty if and only if $U_i^1 > \bar{U}$.

Next, consider a buyer who is matched with a producer at the start of period τ and they are in period t of the current match. Further suppose that they do not separate after demand realization. The rest of period transpires as follows: first, the buyer pays its producer w , then the producer exerts effort e , and finally the producer buyer can terminate the relationship.

¹²Existing economic literature on online platforms largely focuses on platform pricing in the presence of usage and membership externalities (Rochet and Tirole 2003, 2006) and the impact of platforms on consumer search (Brynjolfsson and Smith 2000; Ellison and Ellison 2009). An exception is Hagi and Wright (2015), who model the organizational difference between vertical integration and multi-sided platforms as a difference in the allocation of decision rights, following Gibbons (2005). The role of online platforms as providers of relational trust is emphasized by legal scholars such as Henderson and Churi (2019), but it has received less attention from economic theorists.

Following Board and Meyer-ter-Vehn (2015), we say that strategies are *contract-specific* if (1) the current pay w_{it} only depends on past demand realizations, pay, and effort levels in the current match, $(d_{i1}, w_{i1}, e_{i1}, \dots, d_{i,t-1}, w_{i,t-1}, e_{i,t-1}, d_{it})$, (2) current effort e_{it} additionally depends on w_{it} , (3) separation decisions at the end of the period additionally depend on e_{it} , and (4) separation decisions at the beginning of the next period additionally depend on $d_{i,t+1}$. Contract-specific strategies are thus independent of calendar time τ , the identity of the producer, or histories outside of the current match.

We define a *relational contract* as a subgame-perfect equilibrium in pure, contract-specific strategies where deviations from the equilibrium path are punished in the harshest possible way. In a direct match, this means that the producer shirks and quits if the buyer deviates from equilibrium pay w_{it} ; similarly, the buyer fires the producer if he deviates from equilibrium effort e_{it} . For ease of notation, let w_{it}^d , e_{it}^d , and y_{it}^d denote pay, effort, and output when $d_{it} = d$.

The post-matching continuation payoff for a matched producer when $d_{it} = 1$ is:

$$U_{it}^1 = w_{it}^1 - c(e_{it}^1) + \delta \left[(1 - \alpha_{1i})U_{i,t+1}^1 + \alpha_{1i} \left(\beta_{i,t+1}U_{i,t+1}^0 + (1 - \beta_{i,t+1})\bar{U} \right) \right]. \quad (1)$$

Their post-matching continuation payoff when $d_{it} = 0$ is:

$$U_{it}^0 = w_{it}^0 - c(e_{it}^0) + \delta \left[\alpha_{0i}U_{i,t+1}^1 + (1 - \alpha_{0i}) \left(\beta_{i,t+1}U_{i,t+1}^0 + (1 - \beta_{i,t+1})\bar{U} \right) \right], \quad (2)$$

where β_{it} indicates whether the buyer remains matched with the producer when $d_{it} = 0$.

The post-matching continuation payoff for the buyer when $d_{it} = 1$ is:

$$\Pi_{it}^1 = y_{it}^1 - w_{it}^1 + \delta \left[(1 - \alpha_{1i})\Pi_{i,t+1}^1 + \alpha_{1i} \left(\beta_{i,t+1}\Pi_{i,t+1}^0 + (1 - \beta_{i,t+1})\bar{\Pi}_i^0 \right) \right]. \quad (3)$$

Their post-matching continuation payoff when $d_{it} = 0$ is:

$$\Pi_{it}^0 = y_{it}^0 - w_{it}^0 + \delta \left[\alpha_{0i}\Pi_{i,t+1}^1 + (1 - \alpha_{0i}) \left(\beta_{i,t+1}\Pi_{i,t+1}^0 + (1 - \beta_{i,t+1})\bar{\Pi}_i^0 \right) \right], \quad (4)$$

where $\bar{\Pi}_i^0$ and $\bar{\Pi}_i^1$ are the buyer's pre-matching continuation values when $d_{it} = 0$ and $d_{it} = 1$, respectively. Note that $\bar{\Pi}_i^1 = \Pi_{i1}^1$ and $\bar{\Pi}_i^0 = \Pi_{i1}^0$, since there is an excess of producers in the frictionless matching market, so the buyer can always successfully find a match.

The relational contract must satisfy the following incentive constraints for the producer:

$$U_{it}^1 \geq w_{it}^1 + \delta \bar{U}, \forall t, \quad (\text{P-IC-e})$$

$$U_{it}^1 \geq \bar{U}, \forall t, \quad (\text{P-IC1})$$

$$U_{it}^0 \geq \bar{U}, \forall t. \quad (\text{P-IC0})$$

Constraint (P-IC-e) requires the producer to choose effort over shirking when the service is needed. Constraints (P-IC1) and (P-IC0) require that the producer remain with the current buyer when the demand is 1 or 0, respectively. If $\beta_{it} = 0$, equation (2) and constraint (P-IC0) do not apply, as the buyer immediately separates from the producer when demand is zero.

The relational contracts must also satisfy incentive constraints for the buyer:

$$\Pi_{it}^1 \geq \delta \left[(1 - \alpha_{1i}) \bar{\Pi}_i^1 + \alpha_{1i} \bar{\Pi}_i^0 \right], \quad (\text{B-IC-w1})$$

$$\Pi_{it}^0 \geq \delta \left[(1 - \alpha_{0i}) \bar{\Pi}_i^0 + \alpha_{0i} \bar{\Pi}_i^1 \right], \quad (\text{B-IC-w0})$$

$$\Pi_{it}^1 \geq \bar{\Pi}_i^1, \quad (\text{B-IC1})$$

$$\Pi_{it}^0 \geq \bar{\Pi}_i^0. \quad (\text{B-IC0})$$

Constraints (B-IC-w1) and (B-IC-w2) ensure that the buyer honors the payment to the producer.¹³ Constraints (B-IC1) and (B-IC0) reflect the buyer's desire to retain the producer when there is a demand or not, respectively. As before, if $\beta_{it} = 0$, the term Π_{it}^0 and constraint (B-IC0) do not apply, as the buyer would immediately separate from the producer.

¹³Since the producer exerts effort after the buyer makes the payment, the buyer would not receive the output should the buyer dishonor the payment to the producer. Therefore, there is no output or wage payment in period t on the right hand side of the constraint.

The buyer's problem is to choose a relational contract that maximizes profit Π_{i1}^1 , subject to (B-IC-w), (B-IC1), (P-IC-e), (P-IC1), as well as (B-IC0) and (P-IC0) whenever they apply.

Stationarity

We now show that we can restrict to *stationary* relational contracts—where strategies are time-invariant within a match, i.e., $e_{it}^1 = e_i^1$, $w_{it}^1 = w_i^1$, and $\beta_{it} = \beta_i$, for all t , and when applicable, $e_{it}^0 = e_i^0$ and $w_{it}^0 = w_i^0$ for all t .

Lemma 1. *Assume stationary outside condition $\bar{U}$ and fix a non-stationary relational contract with non-negative profit, $\Pi_{i1}^1 \geq 0$. There is a stationary relational contract that generates a weakly higher profit for the buyer, $\Pi_{i*}^1 \geq \Pi_{i1}^1$.*

Proof. All omitted proofs are in the appendix. □

Intuitively, buyers would like to back-load payments to incentivize effort. Indeed, the optimal contract would be back-loaded if the buyer's outside option were exogenous. However, the outside option here is endogenously determined. If new producers can be hired on back-loaded terms, then the buyer would wish to separate with expensive incumbent producers and replace them with new producers. This argument is originally due to [Shapiro and Stiglitz \(1984\)](#) and is formally shown by [MacLeod and Malcomson \(1989\)](#). Lemma 1 extends the argument to a setting with limited liability and demand fluctuations.

Lemma 1 does not fully rule out non-stationary buyer-optimal contracts. Given any stationary buyer-optimal contract, one can construct a non-stationary buyer-optimal contract by reducing pay and effort in the first period in a way that leaves profits constant. We focus on stationary firm-optimal contracts because, by Lemma 1, non-stationary contracts harm producers without benefiting buyers. Stationary contracts are also analytically tractable.

Two assumptions are made to reflect the large, anonymous nature of the matching market. First, we assume that buyers and producers cannot observe each other's behavior in past relationships. This is important: if producer 2 could observe a buyer's behavior with producer 1, then 2 could punish the buyer for unfairly firing 1, thereby enabling the buyer to

profitably back-load 1's pay. Second, we consider equilibria in contract-specific strategies. If the firm and workers conditioned their behavior on calendar time or the identity of a worker, they could cut payments in the first period of the game for the first producers, without affecting incentives for subsequent producers. We rule out such strategies, since they require the first producer to believe they are special, which is inconsistent with our idea of a large anonymous matching market.

Another important assumption is that the payment w_t is nonnegative. This *limited liability* assumption is made for two reasons. First, it is realistic in many real-world settings. Second, it greatly simplifies the analysis. Because of limited liability, equilibrium pay is always zero during periods when demand is zero (see Lemma A.1). One can thus characterize each buyer's choice between stationary direct and managed contracts simply by comparing the buyer's per-period payment when demand is one.

In addition, we disallow bonus payments, which play an important role in MacLeod and Malcomson (1998) and Levin (2003). In Appendix A.2, we show that this assumption is not critical. The proof extends the argument for a similar result in Board and Meyer-ter-Vehn (2015): For any contract with bonuses, there is a weakly more profitable contract for buyers without bonuses. Intuitively, the buyer prefers to pay the producer at the latest possible moment before e_t . It is therefore weakly profitable to shift the bonus b_{t-1} into the next period's expected pay, such that an proportionately increased amount is paid only if the next period's demand is one and the producer is retained.

Optimal direct relational contract

Lemma 1 enables us to restrict our attention to buyer-optimal, contract-specific, stationary relational contracts. Let $C_i^D = (w_i^1, w_i^0, \beta_i)$ denote such a contract. In this contract, the producer's effort level is one if and only if $d_{it} = 1$, w_i^1 is the payment when $d_{it} = 1$, w_i^0 is the payment when $d_{it} = 0$, and $\beta_i \in \{0, 1\}$ indicates whether buyer i stays with the producer when the buyer's demand is zero. The time subscript is now dropped.

The buyer-optimal direct contract is obtained by choosing w_i^1 , w_i^0 , and β_i to maximize

Π_i^1 , subject to (B-IC-w), (B-IC1), (P-IC-e), (P-IC1), as well as (B-IC0) and (P-IC0) if $\beta_i = 1$.

Lemma 2. *Suppose an optimal direct relational contract exists. Under this relational contract, if*

$$\frac{(1-\delta)\bar{U}}{c} > \frac{\alpha_{0i}}{1-\alpha_{1i}}, \quad (5)$$

then the buyer pays

$$w_{DS}(\alpha_i) = \left(\frac{1}{\delta} \frac{1}{1-\alpha_{1i}} \right) c + (1-\delta)\bar{U}. \quad (6)$$

when demand is one and separates from the producer when demand switches to zero.

Otherwise, the buyer pays

$$w_{DI}(\alpha_i) = \left(\frac{1}{\delta} \frac{1 + \frac{\delta}{1-\delta}\alpha_{0i}}{(1-\alpha_{1i}) + \frac{\delta}{1-\delta}\alpha_{0i}} \right) c + \left(\frac{1 + \frac{\delta}{1-\delta}\alpha_{0i}}{(1-\alpha_{1i}) + \frac{\delta}{1-\delta}\alpha_{0i}} - \delta \right) \bar{U} \quad (7)$$

when demand is one, remains matched with the idle producer when demands switches to zero, and pays zero until demand switches back to one.

Lemma 2 shows that the optimal direct contract features a buyer who either always separates from a producer or always retains him when their demand switches to zero. According to Equation (5), direct contracts with separation dominates direct contracts with idleness when (a) the producer's continuation value when unmatched $\bar{U}$ is high, (b) the buyer has a smaller α_{0i} , so a longer period of idleness is expected, and (c) the buyer has a larger α_{1i} , so a shorter period with service demand is expected.

The payment to producers in a direct contract, $w_D(\alpha_i) \equiv \min\{w_{DS}(\alpha_i), w_{DI}(\alpha_i)\}$, is increasing in α_{1i} . This is because when business needs are shorter-lived, the producer faces a higher chance of either separating or becoming idle, so the future surplus in the relationship is smaller. A higher incentive rent is therefore needed to incentivize producer effort.

4.2 Managed Relational Contracts

In managed matches, buyers enter relational contracts with managers, who are delegated the responsibility of motivating producers. The manager fulfills the buyer's demand by

entering relational (sub-)contracts with a large number of producers and assigning producers to buyers according to demand realization. As we shall show, by aggregating fluctuating buyer demand and coordinating buyer-producer assignments, managers can reduce the cost of motivating producer performance.

To demonstrate this, we first analyze the (sub-)contracts that managers enter with producers. We argue here that unlike buyers, who have fluctuating demand, managers have constant demand for services. Why? In equilibrium, each manager randomly matches with a positive measure of buyers drawn from the same type distribution. Therefore, by the law of large numbers, the total measure of demand that managers receive from buyers is unchanging over time. Given this stable demand for services, the measure of producers that each manager contracts with is equal to the expected measure of demand realizations. Each matched producer in these contracts exert effort in every period.

For tractability, we first assume that each manager enters manager-optimal, contract-specific, and stationary contracts with producers to meet buyer demand. This assumption can be justified by the same argument as in the previous subsection.

Second, we assume that producers are matched in a large anonymous market. This assumption implies that managers will, with positive probability, immediately rematch with producers from whom they just separated, but will not know their histories. This assumption is admittedly unnatural, but it significantly increases analytic tractability, since it enables us to reuse the machinery that we previously developed for direct relational contracts to analyze subcontracts between managers and producers. It is a reasonable approximation when the number of managers is large, but it is problematic when the number of managers is small.

This second assumption can be viewed as yielding a conservative upper bound on the incentive pay required in managed contracts. If matching is not anonymous, managers will never rematch with a producer that it previously fired. Managers can then threaten punishments with greater severity to underperforming producers, since each manager contracts with a nonzero measure of producers. As such, the incentive pay required would be lowered. This is the mechanism highlighted by [Biglaiser and Friedman \(1994\)](#), where

intermediaries offer lower incentive rents to sellers purely due to their market share.¹⁴ Our assumption of anonymity shuts down this additional *market-share* benefit of managed contracts, allowing us to instead focus on the manager's *demand-smoothing* role in fluctuating environments.

Given these assumptions, the payment for the producer is $w_i^1 = w_M$ in every period. By the same logic as Lemma 2, we have that

$$w_M = \frac{c}{\delta} + (1 - \delta)\bar{U}. \quad (8)$$

The demand-smoothing benefit of managed contracts is apparent from Equation (8). Since the managers can aggregate fluctuating demand across their buyers, their payments to producers (w_M) are lower than buyer payments to producers under direct contracts (w_D). Mathematically, $w_D(\alpha_i) \geq w_M$ for all α_i , where equality holds if and only if $\alpha_{1i} = 0$.

Next, we consider how producers are assigned to buyers in each period under the managed contract. Note that buyers are indifferent between any assignment of producers where the assigned producer exerts effort, since producers are identical in our model. Producers are also indifferent between any assignment of buyers where the managers offer the same level of payment. Since managers require producers to exert effort and provide the same compensating payment in every period, buyers and producers have the same payoffs in any assignment where producers are matched with buyers with positive demand in every period. There are an infinite number of such assignments, and any such assignment is optimal. This multiplicity gives rise to a need for each manager to coordinate assignments between their matched buyers and producers. For simplicity, we will not explicitly model the coordination process and instead assume that an optimal assignment is chosen.

Now, we characterize the contract between buyers and managers. The post-matching

¹⁴Biglaiser and Friedman (1994) show middlemen with reputations have a larger incentive to monitor and are in a better position to learn about quality than an ordinary buyer does because they buy a larger proportion of the producers' goods (see also Bardhan, Mookherjee and Tsumagari 2013). Unlike their model, managers do not have reputations in our baseline model; they simply enter relational contracts on both sides of the market.

continuation payoffs for the manager, when the service is and is not needed, respectively, are

$$V_{it}^1 = p_{it}^1 - w_M + \delta \left[(1 - \alpha_{1i})V_i^1 + \alpha_{1i}(\beta_{it}V_{it}^0 + (1 - \beta_{it})\bar{V}) \right], \quad (9)$$

and

$$V_{it}^0 = p_{it}^0 + \delta \left[\alpha_{0i}V_{it}^1 + (1 - \alpha_{0i})(\beta_{it}V_{it}^0 + (1 - \beta_{it})\bar{V}) \right], \quad (10)$$

where $\bar{V}$ is a manager's continuation value after separating from a buyer. The relevant incentive constraints for the manager, similar with those for a producer, are

$$V_{it}^1 \geq p_{it}^1 + \delta \bar{V}, \quad (\text{M-IC-w})$$

$$V_{it}^1 \geq \bar{V}, \quad (\text{M-IC1})$$

$$V_{it}^0 \geq \bar{V}. \quad (\text{M-IC0})$$

For the buyer, the continuation payoffs and incentive constraints are the same as in the direct contract, except that the payments w_i^0 and w_i^1 to the producer are replaced with service fee payments p_i^0 and p_i^1 to the manager. For concision, we omit these conditions, which simply repeat (B-IC-w), (B-IC-1), and (B-IC0).

Unlike producer matches, we assume that matching between buyers and managers is *not* anonymous. If a manager separates from a buyer, it cannot match with a new buyer, because all other potential buyers are matched with some manager and will not become unmatched on the equilibrium path. The manager also cannot re-match with the initial buyer, since manager-buyer matching is assumed to not be anonymous. Therefore, $\bar{V} = 0$ on the equilibrium path.

The assumption of non-anonymous matching is important for our result that managed contracts are sometimes cheaper than direct contracts. Suppose instead that manager matching is anonymous. In this case, a buyer who separates from a manager will immediately rematch with the same manager with positive probability, but the buyer will not know the identity or history of this manager. A larger incentive rent will then be needed to motivate

the manager.

Once again, we assume that buyers enter buyer-optimal, contract-specific, and stationary contracts with manager. Let $C_i^M = (p_i^1, p_i^0, \beta_i)$ denote such a managed relational contract. Here p_i^1 and p_i^0 are the service fees when the buyer needs and does not need the service, respectively. If the buyer deviates from the specified service fee, the manager does not assign a producer to the buyer and separates from the buyer. If instead the producer assigned by the manager deviates from the specified effort, the buyer separates from the manager after production. The optimal managed contract maximizes Π_i^1 subject to these incentive compatibility constraints.

Lemma 3. *Suppose an optimal managed contract exists. Under this contract, the buyer always retains the manager, pays zero service fees to the manager when there is no demand, and when there is demand, she pays the manager a service fee equal to*

$$p(\alpha_i) = \left(\frac{1}{\delta} \frac{1 + \frac{\delta}{1-\delta} \alpha_{0i}}{(1 - \alpha_{1i}) + \frac{\delta}{1-\delta} \alpha_{0i}} \right) w_M. \quad (11)$$

Lemma 3 shows that the cost of managed contract is a form of double marginalization. Note that manager pay $p(\alpha_i)$ is the product of $\lambda(\alpha_i) = \frac{1}{\delta} \frac{1 + \frac{\delta}{1-\delta} \alpha_{0i}}{(1 - \alpha_{1i}) + \frac{\delta}{1-\delta} \alpha_{0i}}$ and producer pay w_M . Here $\lambda(\alpha_i)$ can be thought of as a manager markup. Furthermore, as shown in Equation (8), w_M is elevated above the producer's cost of effort. In other words, both the manager and producer are paid rents so that both are incentivized to honor their contractual obligations.¹⁵

¹⁵This form of double marginalization is different the traditional textbook type. In the classic literature in industrial organization, double marginalization occurs when both upstream and downstream parties possess market power and use restrictive linear contracts. It can thus be eliminated by vertical integration of pricing decision rights, resale-price maintenance, or non-linear pricing (Tirole 1988). In our model, double marginalization instead arises from the non-verifiability of contract performance and the non-transferability of production and monitoring capabilities, as in models of middleman margins (e.g., Biglaiser and Friedman 1994; Bardhan, Mookherjee and Tsumagari 2013). Conventional remedies do not eliminate this form of double marginalization.

Figure 4: Service cost under direct and managed relational contracts

Note: α_1 is the probability that the buyer's demand switches from 1 to 0.

4.3 Optimal Contractual Choice

Having characterized direct and managed contracts, we now characterize when buyers choose managed contracts. We focus on buyers who have the same α_{0i} , which is the rate at which a buyer's demand changes from zero to one. We examine how the optimal contractual choice depends on α_{1i} , the rate at which the buyer's demand changes from one to zero, and $\bar{U}$, the producer's outside option, which in equilibrium reflects whether the producer market is tight and whether it is easy for producers to rematch.

To compare the two, it suffices to compare the payment $w_D(\alpha_i)$ under direct contracting and the service fee $p(\alpha_i)$ under managed contracting. This is because the buyer pays nothing when their demand is zero and can always match with a producer when her demand is one.

Figure 4 provides a graphical illustration. For a buyer with stable demand, i.e., for whom $\alpha_{1i} = 0$, managed contracting is strictly more expensive than direct contracting because of double marginalization. To obtain high-quality services, the buyer needs to pay additional rent to the manager. However, there is no benefit to managed contracts, since demand is stable, so the producer is paid the same incentive rent under direct contracting.

Figure 5: Optimal contractual choice given model parameters

The advantage of managed contracting over direct contracting becomes larger when business needs are short-term. As α_{1i} becomes larger, producers must be paid elevated payments in order for them to exert effort. Since managers can reassign producers across buyers, producers never separate or become idle, so the cost of incentivizing producers is lowered. To see this mathematically, note that $w_{DS}(\alpha_i)$ approaches infinity as α_{1i} approaches one. Furthermore, $p(\alpha_i)$ increases in α_{1i} less steeply than $w_{DI}(\alpha_i)$ if c is relatively small and $\bar{U}$ is relatively large. Therefore, when rematching is easy, the manager operates a more cost-efficient internal producer market by having long-standing relational contracts on both sides of the market.

Figure 5 graphically shows the optimal relational contracts as a function of α_{1i} and $\bar{U}$. In this figure, provided $\bar{U} > \bar{U}^*$, then there exists a cutoff value such that managed contracts dominate if and only if α_{1i} is sufficiently large. If $\bar{U} < \bar{U}^*$, then the producer's pre-matching continuation value is low, so it is optimal to retain them and keep them idle until demand returns.

The following proposition formalizes this result.

Proposition 1. *Take any set of buyers i with the same α_{0i} for whom an optimal contract exists. There exists $\bar{U}^* > 0$ such that:*

1. If $\bar{U} > \bar{U}^*$, there exists $\alpha_1^*(\alpha_{0i}, \bar{U}) \in (0, 1)$ such that a managed contract is optimal if and only if $\alpha_{1i} \geq \alpha_1^*(\alpha_{0i}, \bar{U})$;
2. If $\bar{U} < \bar{U}^*$, a direct contract is optimal for all i in this set.

5 Steady-State Equilibrium

In this section, we show that there exists a unique steady-state equilibrium. We then explore the model's empirical implications. First, we compare the outcomes of managed producers and directly contracted producers in equilibrium. Second, we compare the outcomes and welfare of buyers and producers in economies with and without managers.

5.1 Deriving the Equilibrium

We say that the economy is in a steady state when (1) the number of producers in the economy and the distribution of contracts in the matching market are unchanging across periods and (2) each buyer's demand evolves according to its stationary distribution. By the properties of Markov processes, the steady-state probability that a buyer i has positive demand in any period is equal to $\pi_i = \alpha_{0i} / (\alpha_{0i} + \alpha_{1i})$.

At the start of each period, some buyers and managers are unmatched and open vacancies for unmatched producers. Let $\mathcal{I}_{DS}$ denote the set of buyers who enter direct contracts that end when their demand switches to zero. For a buyer $i \in \mathcal{I}_{DS}$, the steady-state probability that they offer new contracts is

$$v_i = (1 - \pi_i)\alpha_{0i}. \quad (12)$$

Let $\mathcal{I}_{DI}$ be the set of buyers who directly contract with producers in contracts that continue when demand switches. Let $\mathcal{I}_M$ be the set of buyers who contract with managers. For both types of contracts, producers never separate. Therefore, for any buyer $i \in \mathcal{I}_{DI} \cup \mathcal{I}_M$, the steady-state probability that they open a vacancy is $v_i = 0$. The total measure of new

vacancies opened by buyers and managers in the producer market is given by

$$v = \int_{I_{DS}} v_i dF. \quad (13)$$

The steady-state measure of producers in direct contracts, n_B , is given by

$$n_B = \int_{I_{DS}} \pi_i dF + \int_{I_{DI}} dF. \quad (14)$$

The steady-state measure of producers in managed contracts, n_M , is given by¹⁶

$$n_M = \int_{I_M} \pi_i dF. \quad (15)$$

The measure of unmatched producers after matching is

$$n_N = n - n_B - n_M. \quad (16)$$

If y and C are sufficiently large and the buyer type distribution F has full support on $[0, 1] \times [0, 1]$, the value of entering either direct or managed contracts is higher than the value of being unmatched. This implies that there is an excess of producers who enter the producer market, so $n_N > 0$.

Since matching is frictionless, all vacancies opened in the producer market are immediately filled. The total measure of unmatched producers before matching, u , is given by

$$u = v + n_N. \quad (17)$$

Matching is random and vacancies are never filled by producers that are already matched, so the Bellman equation for an unmatched producer is given by

$$\bar{U} = \int_{I_{DS}} \frac{v_i}{u} U_{DS}(\alpha_i) dF + \left(1 - \frac{v}{u}\right) \bar{U}, \quad (18)$$

¹⁶Here π_i enters the integral since the manager aggregates the fluctuating demand of buyers.

where $U_{DS}(\alpha_i) = \frac{1}{1-\delta(1-\alpha_{1i})}(w_{DS}(\alpha_i) - c + \delta\alpha_{1i}\bar{U})$. Note that the continuation value of being unmatched ($\bar{U}$) consists of two components. The first term reflects the rent from matching with an unmatched buyer. The second term reflects the value of remaining unmatched.

To complete the model, we solve for the steady-state number of producers that enter the economy. By assumption, producers enter the economy at the beginning of each period by paying an entry cost C . Entry drives down the likelihood that producers are matched, so they enter only until the continuation value of being unmatched in the labor market equals their entry cost. This yields the following condition:

$$\bar{U} = C. \quad (19)$$

We can now define an equilibrium in our economy.

Definition 1. *A steady-state equilibrium is a distribution of direct and managed relational contracts for buyers such that:*

1. *All relational contracts are buyer-optimal, contract-specific, and stationary;*
2. *Each player's pre-matching continuation value is determined by steady-state transition probabilities and frictionless and random matching via Equation (18);*
3. *The measure of producers in the economy is derived from the producer entry condition, given by Equation (19).*

Proposition 2. *There exists a unique steady-state equilibrium. If y and C are sufficiently high and F has full support on $[0, 1] \times [0, 1]$, then a non-zero measure of buyers enter direct contracts, while another non-zero measure of buyers enter managed contracts.*

Proof. By Equation (19), $\bar{U}$ equals the entry cost C . Given $\bar{U}$, we can compare the values of $w_{DS}(\alpha_i)$, $w_{DI}(\alpha_i)$, $p(\alpha_i)$, and y for each i using Equations (6), (7), and (11) to determine $\mathcal{I}_{DS}$, $\mathcal{I}_{DI}$, and $\mathcal{I}_M$. Having derived these, we can obtain unique values for v_i , v , n_B , and n_M from Equations (12), (13), (14), and (15). We plug these into Equation (18) to solve for a

unique value for u . Plugging u into Equations (16) and (17) then yields a unique value for n . The desired statement then follows from Proposition 1. $\square$

5.2 Empirical Implications

Having shown that there exists a unique steady-state equilibrium in this exchange economy, we can now explore the model's predictions regarding equilibrium behavior.

Effects of managerial coordination on producers

How does managerial coordination affect the pay, separation rates, and idleness of producers? Recent research shows that workers managed by professional service firms earn lower and more compressed wages (Dube and Kaplan 2010; Goldschmidt and Schmieder 2017; Drenik et al. 2023). Some evidence also suggests that they have lower hazard into unemployment than comparable direct employees (Guo, Li and Wong 2024).

Similar patterns are found in our model. To see this, consider the interesting case where all three contract types arise in equilibrium.¹⁷ We define a producer's *separation rate* as the probability that a matched producer becomes unmatched at the start of the next period, and *idleness* as the steady-state probability that a producer is matched but does not exert effort.

Corollary 1. *Directly contracted producers have (1) higher average pay, (2) more dispersed pay, (3) higher separation rates, and (4) higher idleness than managed producers.*

The first result follows from the fact that $w_D(\alpha_i) > w_M$ for all buyers i with fluctuating demand. The second follows from the fact that $w_D(\alpha_i)$ takes on different values depending on α_i , which is heterogeneous across buyers, while w_M is constant. The final two follow from the fact that directly contracted producers may separate from buyers or become idle when demand changes, while managed producers are always reallocated among the manager's clients, so they never separate nor become idle.

¹⁷Specifically, we assume that y , C and F are such that $|I_M|, |I_{DI}|, |I_{DS}| > 0$. If F has full support on $[0, 1] \times [0, 1]$, then by Proposition 1 there exists y and C such that this holds.

Trade and welfare with and without managerial coordination

How does the presence of managers alter market equilibrium and the welfare of buyers and producers? [Felix and Wong \(2024\)](#) show that Brazil's 1993 legalization of professionally managed security firms persistently increased security guard employment, but displaced incumbent security guards from high-wage direct employers.

To explore the same question theoretically, we consider two economies: one with managers and one without. The introduction of managers causes three types of buyers to switch to managed contracts: buyers who do not initially consume services, buyers who initially choose direct contracts with idleness, and buyers who initially choose direct contracts with separation. We denote the three subsets of switching buyers as S_0 , S_I , and S_S . We assume that there is a positive measure of switchers who initially do not consume, and that there is a positive measure of switchers who directly contract initially.¹⁸

In both economies, producers are assumed to freely enter at cost C . As such, the introduction of managers does not alter the payments received by producers who remain directly matched to same buyers. It only reduces the payments received by producers who are become matched to managers instead of buyers. It follows that:

Corollary 2. *When managers are introduced into an economy, the payoffs of all buyers weakly increase and the measure of buyers who receive services increases. The mean pay per unit effort received by producers falls. The total measure of matched producers increases if and only if $\int_{S_0} \pi_i dF > \int_{S_I} (1 - \pi_i) dF$.*

These predictions are intuitive. The introduction of managers benefits buyers with fluctuating demand. As such, it unambiguously increases the measure of buyers who receive services. However, it hurts incumbent producers who were initially earning pay premiums. It is therefore ambiguous whether the measure of matched producers ($n_M + n_B$) increases or falls. On one hand, managers enable more buyers to afford services, which increases demand

¹⁸In other words, y , C and F are such that $|S_0| > 0$ and $|S_I \cup S_S| > 0$. Assuming indifferent buyers do not switch, this requires that there exists $\alpha_i, \alpha'_i \in \text{supp } F$ such that $y > w_D(\alpha_i) > p(\alpha_i)$ and $w_D(\alpha'_i) > y > p(\alpha'_i)$. By Proposition 1, if F has full support on $[0, 1] \times [0, 1]$, then there exist y and C such that this holds.

for producers. On the other, managers reduce idleness, so fewer producers are needed. The relative magnitude of these two effects depends on the distribution of buyer types.

6 Extensions

This section extends the model to study the relationship between managerial coordination and producer specialization. We show that buyers sort into managerial coordination when both demand is volatile and needs are specialized. We also characterize how managerial coordination impacts the division of labor. A further extension with an exogenous producer population are presented in the Appendix and briefly discussed below.

6.1 Producer Specialization

We consider a multi-task economy with a measure of buyers who have unit demand in every period, for either one of two tasks $d_{it} \in \{A, B\}$. Each buyer's demand switches from one task to another task with some symmetric probability α_i at the start of each period.¹⁹ There is also an excess measure of producers indexed by j who choose whether to become either specialists in one of two activities needed by buyers or a generalist with middling skill in both services. Let $\phi_j \in \{A, B, G\}$ denote the chosen type of the producer, where A and B refer to specialists and G refers to the generalist. The output depends on the buyer's demand d_{it} , the producer's type ϕ_j , and the producer's chosen effort e_{jt} , and is given by

$$y_{ijt} = \begin{cases} y + \Delta_i, & \text{if } \phi_j = d_{it} \text{ and } e_{jt} = 1 \\ y, & \text{if } \phi_j = G \text{ and } e_{jt} = 1 \\ 0, & \text{otherwise} \end{cases}$$

where $\Delta_i > 0$ denotes the buyer-specific *gains from specialization*. Output is high when the producer is specialized, demand and the producer's type are well-matched, and effort is high.

¹⁹This is essentially simplifying the model in Section 3 by assuming $\alpha_{Ai} = \alpha_{Bi} = \alpha_i$.

Figure 6: Optimal contractual choice in the presence of gains from specialization

Output is middling for generalists who exert effort, regardless of demand. Output is low if either effort is not made or demand is misaligned with the chosen specialist.

As before, neither pay w nor effort e are contractible and must be incentivized through relational contracts. We assume that output y is sufficiently large so that buyers are always able to receive positive profit by directly contracting with a generalist, so there are never buyers who do not receive services. We also assume that each producer's entry cost C is sufficiently large so that specialist producers never remain in a contract but become idle when the demand of their buyer changes. These assumptions allow us to focus on each buyer's choice between direct contracting with a generalist, direct contracting with a specialist who is never idle, and managed contracting. There are K managers for each task. Each manager can only monitor producers specializing in that task and are randomly matched with buyers who offer managed contracts.²⁰

Drivers of managerial coordination in a multi-task economy

Abraham and Taylor (1996) find that establishments with cyclical demand and specialized needs are more likely to outsource accounting services to professionally managed firms. Similar patterns are found in our model, as visualized in Figure 6 and stated formally below.

²⁰This setup implicitly assumes that each manager specializes in monitoring one type of task.

Proposition 3. *A unique steady-state equilibrium exists in a multi-task economy. Buyer i chooses managed contracts if and only if their demand volatility α_i and gains from specialization Δ_i are both sufficiently large.*

Division of labor with and without managerial coordination

How does managerial coordination affect the division of labor and matching market dynamics? Correlational evidence shows that the rise of professional service firms has coincided with increasingly specialized workers and firms as well as falling unemployment (Katz and Krueger 1999; Song et al. 2019; Handwerker 2023).

To explore the same question theoretically, we compare multi-task economies with and without managers. We assume that the underlying parameters are such that a non-zero measure of buyers choose managed contracts if managers are present and that the conditional distribution of α_i given Δ_i has positive support on $[0, 1]$.

Corollary 3. *When managers are introduced into a multi-task economy, the measure of specialist producers increases and the measure of unmatched producers falls.*

The intuition is as follows. The dashed curve in Figure 6 shows the boundary between direct contracting with a specialist and with a generalist when managers are absent. When managers are present, part of the demand for directly contracted generalists is replaced with demand for managed specialists. Overall demand for specialists rises. In response, more producers choose to become specialists. Correspondingly, there are fewer direct contracts with elevated pay, so fewer producers enter, and the measure of unmatched producers falls.

6.2 Exogenous Producer Population

Appendix C considers a version of the baseline model where the number of producers $n > 1$ is fixed rather than determined by entry. With a fixed producer pool, managers affect the producer outside option $\bar{U}$ by changing aggregate demand for producers, so equilibrium wages and contract choices adjust endogenously. The appendix shows there is a unique

steady-state equilibrium and that, if n is large enough, the market becomes very slack, $\bar{U}$ approaches zero, buyers optimally use direct contracts with idleness, and managerial coordination disappears. Moreover, when managers are introduced with fixed n , they have both direct effects (buyers switching to managed contracts and lowering producer rents) and indirect effects through the induced change in $\bar{U}$, which can raise or lower all producers' pay depending on how many previously unmatched buyers become matched.

7 Conclusion

Economists have long puzzled over why the *visible hand* of managers often replace the *invisible hand* of markets in allocating resources. This paper sheds new light on the puzzle by developing a repeated-game model of an exchange economy in which managers coordinate allocations in decentralized matching markets. We show that managerial coordination reduces the cost of incentivizing performance in fluctuating environments. However, managerial coordination involves a trade-off between demand aggregation and double marginalization. Consequently, managers only partially replace anonymous matching markets in determining assignments between buyers and producers. In equilibrium, buyers sort into managerial coordination and decentralized exchange depending on their demand volatility and their gains from specialization. Managerial coordination alters aggregate output, the division of labor, matching market flows, and the distribution of economic rents.

A key contribution of our work is to show that managerial coordination is efficient in exchange economies, even in the absence of many factors previously hypothesized to be important, including contract-writing costs, bargaining frictions, search frictions, and adverse selection. The predictions of the model are not only applicable to a variety of organizational forms, they are also realistic when compared to recent empirical findings on professional service firms. Further analysis of endogenous relational contracting networks in decentralized matching markets, as attempted in this paper, may be a promising avenue for shedding new light on the equilibrium behavior of economic organizations.

Appendix

A Model with Endogenous Producer Entry

A.1 Proof of Stationarity, Lemma 1

We omit the subscript i in the proofs. To show that it is without loss of generality to focus on stationary relational contracts, we now construct a stationary relational contract $(e_*, w_*^1, w_*^0, \beta_*)$ based on any potentially non-stationary relational contract $(e_t, w_t^1, w_t^0, \beta_t)_t$ that generates a weakly higher continuation payoff for the buyer when starting a relationship, i.e., $\bar{\Pi}_*^1 \geq \bar{\Pi}^1$.

Under $(e_t, w_t^1, w_t^0, \beta_t)_t$, the producer's and the buyer's continuation payoffs in a match are

$$\begin{aligned} U_t^1 &= w_t^1 - c(e_t) + \delta \left[(1 - \alpha_1)U_{t+1}^1 + \alpha_1(\beta_t U_{0,t+1} + (1 - \beta_t)\bar{U}) \right], \\ U_t^0 &= w_t^0 + \delta \left[\alpha_0 U_{t+1}^1 + (1 - \alpha_0)(\beta_t U_{0,t+1} + (1 - \beta_t)\bar{U}) \right], \\ \Pi_t^1 &= y(e_t) - w_t^1 + \delta \left[(1 - \alpha_1)\Pi_{t+1}^1 + \alpha_1(\beta_t \Pi_{0,t+1} + (1 - \beta_t)\bar{\Pi}^0) \right], \\ \Pi_t^0 &= -w_t^0 + \delta \left[\alpha_0 \Pi_{t+1}^1 + (1 - \alpha_0)(\beta_t \Pi_{0,t+1} + (1 - \beta_t)\bar{\Pi}^0) \right]. \end{aligned}$$

The incentive constraints for the producer and the buyer are:

$$\begin{aligned} U_t^1 &\geq w_t^1 + \delta \bar{U}, \\ U_t^1 &\geq \bar{U}, \\ U_t^0 &\geq \bar{U}, \\ \Pi_t^1 &\geq \delta(\alpha_1 \bar{\Pi}^0 + (1 - \alpha_1)\bar{\Pi}^1), \\ \Pi_t^1 &\geq \bar{\Pi}^1, \end{aligned}$$

$$\Pi_t^0 \geq \bar{\Pi}^0.$$

Now we construct $(e_*, w_*^1, w_*^0, \beta_*)$. First, suppose $e_{t'} = 1$ in some period t' and let $e_* = e_{t'} = 1$ (t' exists since otherwise the original relational contract will be a stationary in the effort with effort being 0 in all periods). Second, let $U_*^1 = U_{t'}^1$ and $U_*^0 = U_{t'}^0$. Finally, let $\beta_* = \beta_{t'}$ and set the payments w_*^1 and w_*^0 such that they satisfy:

$$U_*^1 = w_*^1 - c + \delta \left[(1 - \alpha_1)U_*^1 + \alpha_1(\beta_*U_*^0 + (1 - \beta_*)\bar{U}) \right],$$

$$U_*^0 = w_*^0 + \delta \left[\alpha_0U_*^1 + (1 - \alpha_0)(\beta_*U_*^0 + (1 - \beta_*)\bar{U}) \right].$$

The buyer's continuation payoffs are thus

$$\Pi_*^1 = y - w_*^1 + \delta \left[(1 - \alpha_1)\Pi_*^1 + \alpha_1(\beta_*\Pi_*^0 + (1 - \beta_*)\bar{\Pi}^0) \right],$$

$$\Pi_*^0 = -w_*^0 + \delta \left[\alpha_0\Pi_*^1 + (1 - \alpha_0)(\beta_*\Pi_*^0 + (1 - \beta_*)\bar{\Pi}^0) \right].$$

Under this new stationary relational contract, the producer's incentive constraints are satisfied. Indeed, the first incentive constraint requires

$$\delta \left[(1 - \alpha_1)(U_*^1 - \bar{U}) + \alpha_1\beta_*(U_*^0 - \bar{U}) \right] \geq c,$$

as $\delta \left[(1 - \alpha_1)(U_{t'}^1 - \bar{U}) + \alpha_1\beta_{t'}(U_{t'}^0 - \bar{U}) \right] \geq c(e_{t'})$ at t' . Meanwhile, we know

$$U_*^1 = U_{t'}^1 \geq \bar{U},$$

$$U_*^0 = U_{t'}^0 \geq \bar{U},$$

The buyer's incentive constraints are satisfied since the relational contract is stationary, which implies $\Pi_*^1 = \bar{\Pi}^1$ and $\Pi_*^0 = \bar{\Pi}^0$ in this frictionless market with excess supply of producers.

To show $\bar{\Pi}_*^1 \geq \bar{\Pi}^1$, given that $\bar{\Pi}_*^1 = \Pi_*^1$ and $\Pi_{t'}^1 \geq \bar{\Pi}^1$, we need only to show $\Pi_*^1 \geq \Pi_{t'}^1$. We do so by comparing the joint surpluses $\Pi_*^1 + U_*^1$ and $\Pi_{t'}^1 + U_{t'}^1$. It is obvious that

$\Pi_*^1 + U_*^1 \geq \Pi_{t'}^1 + U_{t'}^1$, since under the stationary relational contract, effort is motivated and thus the flow payoffs are maximized in each period when there is demand. Given that $U_*^1 = U_{t'}^1$ by construction, we have $\Pi_*^1 \geq \Pi_{t'}^1$.

A.2 Irrelevance of bonus payments

Based on the relational contract with bonus payments $(e_t, w_t^1, b_t^1, w_t^0, b_t^0, \beta_t)_t$, we can construct a new relational contract without bonus payments that generates the same continuation payoffs for the buyer, $(\hat{w}_t^1, \hat{w}_t^0, \hat{\beta}_t)_t$, by shifting the bonus payments in the last period to the next period with adjusting to discounting and potential separation.

Specifically, let $\hat{w}_t^1 = w_t^1 + \frac{(1-\alpha_0)\frac{b_t^1}{\delta} - \alpha_1\frac{b_t^0}{\delta}}{1-\alpha_0-\alpha_1}$, $\hat{w}_t^0 = w_t^0 + \frac{(1-\alpha_1)\frac{b_t^0}{\delta} - \alpha_0\frac{b_t^1}{\delta}}{1-\alpha_0-\alpha_1}$, and $\hat{\beta}_t = \beta_t, \forall t$. By doing so, all the incentive constraints are satisfied since the following conditions are satisfied:

$$\begin{aligned} -b_t^1 + \delta \left[(1-\alpha_1)\Pi_{t+1}^1 + \alpha_1(\beta_{t+1}\Pi_{0,t+1} + (1-\beta_{t+1})\bar{\Pi}^0) \right] &= \delta \left[(1-\alpha_1)\hat{\Pi}_{t+1}^1 + \alpha_1(\hat{\beta}_{t+1}\hat{\Pi}_{0,t+1} + (1-\hat{\beta}_{t+1})\bar{\Pi}^0) \right] \\ -b_t^0 + \delta \left[\alpha_0\Pi_{t+1}^1 + (1-\alpha_0)(\beta_{t+1}\Pi_{0,t+1} + (1-\beta_{t+1})\bar{\Pi}^0) \right] &= \delta \left[\alpha_0\hat{\Pi}_{t+1}^1 + (1-\alpha_0)(\hat{\beta}_{t+1}\hat{\Pi}_{0,t+1} + (1-\hat{\beta}_{t+1})\bar{\Pi}^0) \right]. \end{aligned}$$

Under this relational contract without bonus payments, the buyer's continuation payoffs stay the same as the original relational contract with bonus payments. Since the total surplus does not change, the producer's continuation payoffs also stay the same, indicating that the producer's incentive constraints are satisfied. It is therefore without loss to focus on relational contracts without bonus payments.

A.3 Implications of Limited Liability

We establish the following two lemmas.

Lemma A.1. *Suppose an optimal bilateral relational contract exists. Under this contract, if $\beta > 0$, then the following three conditions hold: 1) $w^0 = 0$, 2) both (B-IC1) and (B-IC0) bind, and 3) (P-IC1) is slack.*

Proof. Prove by contradiction. Suppose that $w^0 > 0$. Since there is an excess of producers in the matching market, $\bar{\Pi}^1 = \Pi^1$. So $\Pi^0 = -w^0 + \delta \left[\alpha_0 \Pi^1 + (1 - \alpha_0)(\beta \Pi^0 + (1 - \beta)\bar{\Pi}^0) \right] = -w^0 + \delta \left[\alpha_0 \bar{\Pi}^1 + (1 - \alpha_0)(\beta \Pi^0 + (1 - \beta)\bar{\Pi}^0) \right]$. Also note that $\bar{\Pi}^0 = \delta \left[\alpha_0 \bar{\Pi}^1 + (1 - \alpha_0)\bar{\Pi}^0 \right]$. Therefore, $\Pi^0 - \bar{\Pi}^0 = -w^0 + \delta(1 - \alpha_0)\beta(\Pi^0 - \bar{\Pi}^0) < \delta(1 - \alpha_0)\beta(\Pi^0 - \bar{\Pi}^0)$, where the inequality comes from $w^0 > 0$. Since $\delta \in (0, 1)$ and $\beta \in (0, 1]$, we discuss whether $\alpha_0 = 1$. If $\alpha_0 < 1$, the inequality cannot be satisfied, contradicting $w^0 > 0$. If $\alpha_0 = 1$, $\bar{\Pi}^0 = \delta \bar{\Pi}^1$ and then $\Pi^0 = -w^0 + \delta \bar{\Pi}^1 < \bar{\Pi}^0$, which contradicts (B-IC0) and also indicates that $w^0 = 0$. Therefore, $w^0 = 0$ and $\Pi^0 = \bar{\Pi}^0$. Thus both (B-IC1) and (B-IC0) bind.

We now show that (P-IC1) is slack. Suppose it binds, so $U^1 = \bar{U}$. Then given $w^0 = 0$ and $\delta < 1$, plug in $U^1 = \bar{U}$ and get $U^0 = \delta \left[\alpha_0 \bar{U} + (1 - \alpha_0)(\beta U^0 + (1 - \beta)\bar{U}) \right] < (1 - \alpha_0)\beta U^0 + (1 - (1 - \alpha_0)\beta)\bar{U}$. This inequality implies that $U^0 < \bar{U}$, which contradicts (P-IC0). So (P-IC1) is slack. $\square$

Lemma A.2. *For any buyer who directly contracts with producers, maximizing Π^1 is equivalent to minimizing w^1 .*

Proof. Based on Lemma A.1, the buyer's continuation payoffs can be written as $\Pi^1 = \frac{1 - \delta(1 - \alpha_0)}{1 - \delta\alpha_0\alpha_1 - \delta(2 - \alpha_0 - \alpha_1) + \delta^2(1 - \alpha_0)(1 - \alpha_1)}(y - w^1)$, and $\Pi^0 = \frac{\delta\alpha_0}{1 - \delta(1 - \alpha_0)}\Pi^1$. Since $\frac{\partial \Pi^1}{\partial w^1} < 0$, a buyer's problem is equivalent to minimize w^1 subject to producer's incentive constraints. $\square$

A.4 Proof of Optimal Direct Contract, Lemma 2

For simplicity, we write w^1 as w in the rest of the proof. We complete the proof by analyzing and comparing the terms in the buyer-optimal relational contract under $\beta = 0$ and $\beta = 1$.

Choice 1: $\beta = 0$. If $\beta = 0$, $U^1 = w - c + \delta \left[(1 - \alpha_1)U^1 + \alpha_1 \bar{U} \right]$. The buyer optimally chooses w subject to a binding (P-IC-e), which gives $w_{DS} = \frac{1}{\delta(1 - \alpha_1)}c + (1 - \delta)\bar{U}$.

Choice 2: $\beta = 1$. If $\beta = 1$, the buyer's optimization problem becomes $\min_w w$ subject to (P-IC-e), (P-IC0), (1), (2), and $w \geq 0$.

The Lagrangian is given by

$$L = w + \lambda_1(U^1 - (w - c + \delta((1 - \alpha_1) \cdot U^1 + \alpha_1(U^0)))) \\ + \mu_1(w + \delta\bar{U} - U^1) + \mu_2(\bar{U} - U^0) + \mu_3(-w).$$

The Kuhn-Tucker conditions are given by $\frac{\partial L}{\partial w} = 1 + \mu_1(1 - \frac{\partial U^1}{\partial w}) - \mu_2 \frac{\partial U^0}{\partial w} - \mu_3 \leq 0$; $\frac{\partial L}{\partial w} w = 0$; $\lambda_1 > 0$, $\mu_1, \mu_2, \mu_3 \geq 0$; $\mu_1(w + \delta\bar{U} - U^1) = 0$; $\mu_2(\bar{U} - U^0) = 0$; and $\mu_3 w = 0$.

By taking derivatives on both sides of equations (1) and (2) with respect to w , we get

$$\frac{\partial U^1}{\partial w} = 1 + \delta \left[(1 - \alpha_1) \frac{\partial U^1}{\partial w} + \alpha_1 \beta \frac{\partial U^0}{\partial w} \right], \quad (\text{A1})$$

$$\frac{\partial U^0}{\partial w} = \delta \left[\alpha_0 \frac{\partial U^1}{\partial w} + (1 - \alpha_0) \beta \frac{\partial U^0}{\partial w} \right]. \quad (\text{A2})$$

We proceed by the following steps.

Step 1: Show that $\mu_3 = 0$ and $w > 0$. Suppose that $w = 0$. Then

$$U^1 = -c + \delta \left[(1 - \alpha_1)U^1 + \alpha_1 U^0 \right] < (1 - \alpha_1)U^1 + \alpha_1 U^0,$$

where the inequality comes from that $c > 0$ and $\delta < 1$. The inequality above implies that $U^1 < U^0$. Meanwhile,

$$U^0 = \delta \left[\alpha_0 U^1 + (1 - \alpha_0)U^0 \right] < \alpha_0 U^1 + (1 - \alpha_0)U^0 < U^0,$$

where the first inequality comes from $\delta < 1$ and the second inequality comes from $U^1 < U^0$. Since $U^0 < U^0$ can never be true, we know that $w > 0$ and thus $\mu_3 = 0$.

The implication for $w > 0$ is that $\frac{\partial L}{\partial w} = 1 + \mu_1(1 - \frac{\partial U^1}{\partial w}) - \mu_2 \frac{\partial U^0}{\partial w} = 0$.

Step 2: Discuss the values of μ_1 and μ_2 . **Case 1)** $\mu_1 = \mu_2 = 0$. In this case, $\frac{\partial L}{\partial w} = 0$ is violated, indicating that this case is not possible.

Case 2) $\mu_1 = 0$ and $\mu_2 > 0$. In this case, $U^1 > w + \delta\bar{U}$ and $U^0 = \bar{U}$. Solve U^1 and w based on equation (1), and we get $U^1 = \frac{1-\delta(1-\alpha_0)}{\delta\alpha_0}\bar{U}$, and $w = c + \frac{(1-\delta)^2 - \delta(1-\delta)(\alpha_0 + \alpha_1)}{\delta\alpha_0}\bar{U}$. Meanwhile, $\frac{\partial L}{\partial w} = 0$ and $\mu_1 = 0$ imply that $1 = \mu_2 \frac{\partial U^0}{\partial w}$.

There are two conditions that need to be satisfied for this case to be feasible and optimal. First, for feasibility, the solved w and U^1 need to satisfy $U^1 > w + \delta\bar{U}$. After plugging in U^1 and w as functions of $\bar{U}$, this requires that $\frac{(1-\delta)\bar{U}}{c} > \frac{\alpha_0}{1-\alpha_1}$. Second, since we are considering the case where choosing $\beta = 10$ is weakly better than choosing $\beta = 0$, the solved w needs to be lower than w_{DS} , which gives $\frac{(1-\delta)\bar{U}}{c} \leq \frac{\alpha_0}{1-\alpha_1}$. These two conditions contract each other, indicating that this case is not possible.

Case 3) $\mu_1 > 0$ and $\mu_2 > 0$. In this case, both incentive compatibility constraints bind, which give $U^1 = w + \delta\bar{U}$ and $U^0 = \bar{U}$. Under binding (P-IC-e) and (P-IC0), equations (1) and (2) can be satisfied only if $\frac{(1-\delta)\bar{U}}{c} = \frac{\alpha_0}{1-\alpha_1}$. In that case, the solved w also coincides with w_{DS} , and a buyer is thus indifferent between $\beta = 1$ and $\beta = 0$.

Case 4) $\mu_1 > 0$ and $\mu_2 = 0$. In this case, $U^1 = w + \delta\bar{U}$. Solve U^1 and w based on equation (1), and we obtain $w = w_{DI} \equiv \left(\frac{1}{\delta} \frac{1 + \frac{\delta}{1-\delta}\alpha_0}{(1-\alpha_1) + \frac{\delta}{1-\delta}\alpha_0} \right) c + \left(\frac{1 + \frac{\delta}{1-\delta}\alpha_0}{(1-\alpha_1) + \frac{\delta}{1-\delta}\alpha_0} - \delta \right) \bar{U}$.

In sum, if a buyer chooses $\beta = 1$, she pays w_{DI} when her demand is 1.

The comparison between choice 1 and choice 2 hinges on comparing w_{DS} and w_{DI} . It can be shown that $w_{DS} < w_{DI}$ if and only if $\frac{(1-\delta)\bar{U}}{c} > \frac{\alpha_0}{1-\alpha_1}$. Therefore, whenever the condition above holds, the buyer chooses $\beta = 0$ (separating from the producer when demand becomes 0) and pays w_{DS} when her demand is 1. Otherwise, she chooses $\beta = 1$ (retaining the producer when demand becomes 0) and pays w_{DI} when her demand is 1.

A.5 Proof of Optimal Managed Contract, Lemma 3

Observe that the continuation payoffs and incentive compatibility constraints for a manager in a managed contract are similar with those for a producer in a direct contract. The only differences are that the “cost of production” for a manager is w_M and its continuation value after separating from a buyer, given by $\bar{V}$, is 0. Since $\frac{(1-\delta)\bar{V}}{w_M} \leq \frac{\alpha_0}{1-\alpha_1}$ for any α_0 and α_1 . Therefore, the value of p is determined by replacing c with w_M and $\bar{U}$ with 0 in w_{DI} .

A.6 Proof of Optimal Contractual Choice, Proposition 1

Step 1: Compare direct contract with separation and direct contract with idleness.

From Lemma 2, it is immediate that if $\bar{U} > \bar{U}^{ei} \equiv \frac{c}{1-\delta}\alpha_0$, there exists a unique cutoff $\bar{\alpha}^{1ei} \in (0, 1)$ such that $w_{DS} < w_{DI}$ if and only if $\alpha_1 < \bar{\alpha}^{1ei}$.

Step 2: Compare direct contract with separation with managed contract. Observe that $w_{DS} < p$ if and only if $f(\alpha_1) \equiv \frac{1}{1-\alpha_1}\frac{c}{\delta} + (1-\delta)\bar{U} - \frac{1}{\delta - \frac{1}{1+\frac{\delta}{1-\delta}\alpha_0}\alpha_1}(\frac{c}{\delta} + (1-\delta)\bar{U}) < 0$. Observe that, when $\alpha_0 = 0$, $f(\alpha_1)|_{\alpha_0=0} = (1 - 1/\delta)\frac{c}{\delta}\frac{1}{1-\alpha_1} + (1 - \frac{1}{\delta(1-\alpha_1)})(1-\delta)\bar{U} < 0$. In this case, $w_{DS} < p$ for sure, so $\bar{\alpha}^{eo1} = 1$. When $\alpha_0 > 0$, observe that $f(0) = (1 - \frac{1}{\delta})\kappa < 0$, and $f(1)$ goes to infinity. We now show that the continuous function $f(\alpha_1)$ intersects with 0 only once. Note that $\frac{\partial f(\alpha_1)}{\partial \alpha_1} = \frac{\zeta(\zeta\frac{c}{\delta} - \kappa)\alpha_1^2 - 2(c-\kappa)\zeta\alpha_1 + (\delta c - \zeta\kappa)}{(1-\alpha_1)^2(\delta - \zeta\alpha_1)^2}$, where $\zeta = \frac{\delta}{1+\frac{\delta}{1-\delta}\alpha_0}$ and $\kappa = \frac{c}{\delta} + (1-\delta)\bar{U}$. Observe that the numerator is a quadratic equation, where the coefficient of α_1^2 is negative, the coefficient of α_1 is positive, and the constant $\delta c - \zeta(\frac{c}{\delta} + (1-\delta)\bar{U})$ can be positive or negative. Therefore, $f(\alpha_1)$ is either strictly increasing, or is first decreasing then increasing. In either case, $f(\alpha_1)$ intersects with 0, with the intersect being $\bar{\alpha}^{eo1} \in (0, 1)$. In sum, there exists a unique cutoff $\bar{\alpha}^{eo1} \in (0, 1]$ such that $w_{DS} < p$ if and only if $\alpha_1 < \bar{\alpha}^{eo1}$.

Step 3: Compare direct contract with idleness and managed contract. Observe that $w_{DI} < p$ if and only if $g(\alpha_1) \equiv \frac{1+\frac{\delta}{1-\delta}\alpha_0}{1+\frac{\delta}{1-\delta}\alpha_0-\alpha_1}(\frac{2\delta-1}{\delta}\bar{U} - \frac{1-\delta}{\delta}\frac{c}{\delta}) < \delta\bar{U}$. Observe that $g(0) = \frac{2\delta-1}{\delta}\bar{U} - \frac{1-\delta}{\delta}\frac{c}{\delta}$ and $g(1) = \frac{1+\frac{\delta}{1-\delta}\alpha_0}{\frac{\delta}{1-\delta}\alpha_0}(\frac{2\delta-1}{\delta}\bar{U} - \frac{1-\delta}{\delta}\frac{c}{\delta})$. Also observe that $g(0) - \delta\bar{U} = \frac{-(1-\delta)^2}{\delta}\bar{U} - \frac{1-\delta}{\delta}\frac{c}{\delta} < 0$. If $\bar{U} < \bar{U}^{io} \equiv \frac{(1-\delta)(1-\alpha_0)c}{\delta(2-(1-\delta)\alpha_0)-1}$, $g(1) < \delta\bar{U}$ and thus the inequality holds for sure. Otherwise, since $g(\alpha_1)$ is strictly increasing in α_1 , by the intermediate value theorem, there exists a unique cutoff $\bar{\alpha}^{io1} \in (0, 1)$ such that $w_{DI} < p$ if and only if $\alpha_1 < \bar{\alpha}^{io1}$. Otherwise, $w_{DI} < p$ for sure.

Step 4: Put it together. Let $\bar{U}_* = \bar{U}^{io}$ and $\alpha_* = \min\{\bar{\alpha}^{io1}, \bar{\alpha}^{eo1}\}$. If $\bar{U} < \bar{U}^{io}$, $w_{DI} < p$ by Step 3. Otherwise, if $\bar{U} \geq \bar{U}^{io}$ there are two cases. If $w_{DS} < w_{DI}$, managed contract is optimal when $p < w_{DS}$, namely when $\alpha_1 > \bar{\alpha}^{1eo}$. If $w_{DS} > w_{DI}$ managed contract is optimal when $p < w_{DI}$, namely when $\alpha_1 > \bar{\alpha}^{1io}$.

A.7 Proof of Cross-sectional Comparisons, Corollary 1

First, note that $w_D(\alpha_i) > w_M$ for all $i \in \mathcal{I}_{DS} \cup \mathcal{I}_{DI}$. Therefore, $E[w_D(\alpha_i) \mid i \in \mathcal{I}_{DS} \cup \mathcal{I}_{DI}] > E[w_M \mid i \in \mathcal{I}_M]$. Second, note that $w_D(\alpha_i)$ takes on different values depending on α_i , which is heterogeneous across buyers, while w_M is constant. Therefore, $\text{Var}[w_D(\alpha_i) \mid i \in \mathcal{I}_{DS} \cup \mathcal{I}_{DI}] > \text{Var}[w_M \mid i \in \mathcal{I}_M] = 0$. Third, the separation rate is given by $\beta_i \alpha_{1i}$. Note that $\beta_i = 1$ for all $i \in \mathcal{I}_{DI}$, while $\beta_i = 0$ for all $i \in \mathcal{I}_{DS} \cup \mathcal{I}_M$. Fourth, the idleness for a buyer $i \in \mathcal{I}_{DI}$ is given by $(1 - \pi_i)(1 - \omega_i) > 0$. By contrast, for $i \in \mathcal{I}_{DS} \cup \mathcal{I}_M$, idleness is zero.

A.8 Proof of Managerial Impacts, Corollary 2

With the introduction of managers, the per-period payoff of buyer $i \in \mathcal{S}^0$ increases by $y - p(\alpha_i)$. The per-period payoff of buyer $i \in \mathcal{S}_I$ increases by $w_{DI}(\alpha_i) - p(\alpha_i)$. The per-period payoff of buyer $i \in \mathcal{S}_S$ increases by $w_{DS}(\alpha_i) - p(\alpha_i)$. The per-period payoff of the remaining buyers are unchanged. The average producer pay per unit effort falls, since $w_D(\alpha_i) > w_M$ for all $i \in \mathcal{S}_I \cup \mathcal{S}_S$. Producer separation rates and idleness also fall, since buyers switch from direct contracts with either idleness and separation to managed contracts in which buyers are never idle and never separate. The measure of buyers who receive services increases by $|\mathcal{S}^0|$. The total measure of services provided in the economy increases by $\int_{\mathcal{S}^0} \pi_i dF$. However, for $i \in \mathcal{S}_I$, the steady-state measure of producers matched to these buyers fall, since idleness falls. The total measure of matched producer ($n_M + n_B$) therefore increases if and only if $\int_{\mathcal{S}^0} \pi_i dF > \int_{\mathcal{S}_I} (1 - \pi_i) dF$.

B Model with Producer Specialization

B.1 Proof of Equilibrium with Specialization, Proposition 3

Based on Lemma 2 and 3, the buyer's post-matching continuation payoffs when she has demand is $\Pi_D(\alpha_i) = \frac{y + \Delta_i}{1 - \delta} - \left[\bar{U} + \frac{c}{(1 - \alpha_i)\delta(1 - \delta)} \right]$ if directly contracting with a specialist producer. It is $\Pi_G = \frac{y}{1 - \delta} - \left[\bar{U} + \frac{c}{\delta(1 - \delta)} \right]$, if directly contracting with a generalist producer. It

is $\Pi_M(\alpha_i) = \frac{y+\Delta_i}{1-\delta} - \left[\frac{1}{\delta} \frac{1+\frac{\delta}{1-\delta}\alpha_i}{1+\frac{\delta}{1-\delta}\alpha_i-\alpha_i} (\bar{U} + \frac{c}{\delta(1-\delta)}) \right]$ if contracting with a manager.

Three observations follow. First, a buyer prefers to directly contract with a specialist than directly contract with a generalist if and only if $\Pi_B(\alpha_i) \geq \Pi_G$, or, $\Delta_i \geq \frac{\alpha_i}{1-\alpha_i} \frac{c}{\delta}$. Second, a buyer prefers to directly contract with specialists rather than contract with a manager if and only if $\left[\frac{1}{\delta} \frac{1+\frac{\delta}{1-\delta}\alpha_i}{1+\frac{\delta}{1-\delta}\alpha_i-\alpha_i} - 1 \right] \left[\bar{U} + \frac{c}{\delta(1-\delta)} \right] \geq \frac{\alpha_i}{1-\alpha_i} \frac{c}{\delta(1-\delta)}$. By Proposition 1, there exists a unique cutoff α^{ei} such that the buyer prefers to contract with a manager if and only if $\alpha_i > \alpha^{ei}$. Third, a buyer prefers a managed contract over direct contract with a generalist if and only if $\Delta_i \geq \bar{\Delta}(\alpha_i) \equiv \left[\frac{1}{\delta} \frac{1+\frac{\delta}{1-\delta}\alpha_i}{1+\frac{\delta}{1-\delta}\alpha_i-\alpha_i} - 1 \right] \left[\bar{U} + \frac{c}{\delta(1-\delta)} \right]$. Therefore, the buyer choose to contract with a manager if and only if α_i and Δ_i are both large enough.

B.2 Proof of Managerial Impacts with Specialization, Corollary 3

Let S_G denote buyers who switch from direct contracts with generalists to managed contracts with specialists when managers become available. Let S_B be the set of buyers who switch from direct contracts with specialists to managed contracts with specialists. Given the assumption on the distribution of (Δ_i, α_i) , $|S_G|, |S_B| > 0$. The contractual choice of the remaining buyers are unchanged. Therefore, the measure of specialists unambiguously increase with managerial coordination.

The Bellman equation for unmatched producers can be rewritten as $\bar{U} = \frac{v}{u} \frac{E[v_i U_{1i}]}{v} + (1 - \frac{v}{u}) \delta \bar{U}$. With the introduction of managers, more producers are contracted as specialists under managed contracts without separation, so v and $E[v_i U_{1i}]$ both fall. This implies that $\frac{v}{u}$ increases. It follows that the measure of unmatched producers $n_N = u - v$ falls.

C Model with Exogenous Producer Population

The main text assumed that the number of producers is determined via endogenous entry. In this appendix, we analyze an economy where the number of producers is fixed exogenously at $n > 1$. The main difference is that when the producer population is fixed, the presence of managers alters $\bar{U}$ by changing the overall demand for producers, and thereby alters

equilibrium outcomes.

We first show that if n is sufficiently large, then the producer market becomes very slack, buyers prefer to enter contracts with idleness, and there is no managerial coordination.

Proposition C.1. *Assume the number of producers n is exogenously fixed. There exists a unique steady-state equilibrium. If n is sufficiently large, then there are no managed contracts.*

Proof. Given $\bar{U}$, we can compare the values of $w_{DS}(\alpha_i)$, $w_{DI}(\alpha_i)$, $p(\alpha_i)$, and y for each i using (6), (7), and (11) to determine $\mathcal{I}_{DS}$, $\mathcal{I}_{DI}$, and $\mathcal{I}_M$. Having derived these, we can obtain unique values for v_i , v , n_B , and n_M from (12), (13), (14), and (15). Plugging $w_{DS}(\alpha_i)$, $w_{DI}(\alpha_i)$, and $w_M(\alpha_i)$ into (18) yields a contraction mapping. Therefore a unique fixed point for $\bar{U}$ exists. By (16), (17), and (18), $\bar{U}$ is decreasing in n , and $\bar{U} \rightarrow 0$ as $n \rightarrow \infty$. The desired result follows by Proposition 1. $\square$

We next compare economies with and without managers assuming that n is fixed and that some nonzero measure of buyers choose managerial coordination when possible. In this economy, introducing managers has both direct and indirect effects. The direct effect holds $\bar{U}$ fixed and was characterized in the previous subsection. Due to this effect, various types of buyers switch to managerial coordination, producer rents fall, and the number of matched producers may or may not increase. Without free entry, however, $\bar{U}$ also adjusts. A change in $\bar{U}$ affects all of the endogenous variables in the model, so managerial coordination has indirect spillover effects onto all producers.

The sign of the resulting change in $\bar{U}$ depends on the distribution of buyer types α_i . If a large set of buyers switch from being unmatched to matched, then $\bar{U}$ would increase due to reduced wait time in a tightened producer market. This indirect effect raises the pay of all producers. On the other hand, if no buyers switch from being unmatched to being matched, then $\bar{U}$ would unambiguously fall due to producer rent reductions associated with initially matched buyers switching to managerial coordination. This indirect effect instead reduces the pay of all producers.
